## The brain: plasticity and stability?

- Learning occurs all the time.
- In fact, whole synapses are formed and removed all the time<sup>4</sup>: **structural plasticity**.
- Unregulated brain activity causes disorders: **epilepsy**.
- So, how does the brain remain **stable** despite changing all the time?
- Stabilising (**homeostatic**) processes<sup>5</sup>?

## Our investigations: computational modelling

- We made a **new computer model** of a small part of the brain.
- We **replicated** what biologists observed in their laboratories.
- We **tested different ways** in which homeostatic structural plasticity may occur.
- We will now **send our ideas back to biologists** for validation.

## Our model suggests that: I

- Neurons modify their **dendrites (inputs)** to maintain their activity.
- Too much: reduce excitatory inputs, increase inhibitory inputs.
- Too less: vice versa.

## Our model suggests that: II

- Neurons modify their **axons (outputs)** to transfer their activity.
- Too much excitation: pass on to neighbours.
- Too much inhibition: pass on to neighbours.

## What next?

- Investigate **functional consequences** of homeostatic structural plasticity: does the part of the brain behave the same after repair?
- **Further investigation** with more detailed modelling: move from simple point neuron models to more realistic multi-compartmental models.

## Summary

- The brain is **plastic but stable**.
- Neurons form and remove synapses all the time—continuously modifying brain networks.
- We investigated how the brain remains stable.
  - Homeostatic Structural Plasticity.
  - We developed a new, realistic computer model of brain injury.
  - Our simulations suggest that neurons maintain their own activity by forming and removing inputs, and transferring their states to other neurons.
